Business Insights

Page 1 - User Activity Overview Dashboard

1. Average daily steps (~7.7K) are below the recommended 10K benchmark.
2. Average sleep duration (~419 minutes) is slightly below the optimal 7 – 9 hour range.
3. There is a strong positive correlation between steps taken and calories burned.
4. Most user activity falls under light and sedentary intensity levels.
5. A small group of users contributes disproportionately to the highest activity levels.
6. Daily step counts fluctuate across months, indicating inconsistent user activity patterns.
7. Moderate activity users represent a significant and consistent engagement segment.
8. The average BMI (25.19) indicates many users fall into the borderline overweight category.
9. Average weight (~72 kg) suggests general fitness levels but with potential for improvement.
10. User engagement is uneven, with a clear gap between highly active and minimally active users.

Page 2 - Sleep vs Activity Insights Dashboard

1. Average sleep duration is around 419 minutes (~7 hours), indicating moderate sleep levels among users.
2. Users spend more time in bed (~459 minutes) than actual sleep time, showing a gap between rest time and effective sleep.
3. Sleep efficiency of 0.91 (91%) suggests relatively good sleep quality for most users.
4. The average BMI of 25.19 indicates many users fall into the borderline overweight category.
5. Calorie burn remains relatively high even when sleep duration varies, suggesting sleep does not strongly impact calorie burn in the short term.
6. Sleep vs Time in Bed comparison shows consistent gaps between time in bed and actual sleep minutes across dates.
7. Some users with higher BMI values show shorter sleep durations, indicating a possible relationship between sleep patterns and BMI.
8. Sleep duration trends fluctuate across different dates, showing inconsistent sleep patterns among users.
9. Sleep duration remains relatively stable across different activity types, with no extreme variations between sedentary and active users.
10. The dataset records multiple sleep logs per user, indicating regular sleep tracking behaviour among users.

Page 3 - Fitness & Health Indicators Dashboard

1. Users spend the majority of their time in sedentary activity (~991 minutes) compared to other activity levels.
2. Light activity (~193 minutes) forms the second-largest share of daily user activity.
3. Moderate activity levels (~13.5 minutes) are significantly lower than light activity.
4. Very active minutes (~21 minutes) remain relatively low across users.
5. Activity distribution shows a balanced segmentation across activity types, but actual intensity minutes differ significantly.
6. High vs Light activity comparison indicates light activity consistently dominates over very active workouts.
7. Moderate vs Sedentary comparison highlights sedentary behaviour being substantially higher than moderate activity levels.
8. Daily activity trends show stable light activity patterns but minimal variation in very active minutes.
9. Total steps across selected days remain consistently high (~0.26M–0.28M), indicating steady user engagement in walking activities.
10. Average fat level (~23.5) suggests moderate body fat levels among the tracked users.
